Pandas

As described at https://pandas.pydata.org (https://pandas.pydata.org (https://pandas.pydata.org (https://pandas.pydata.org (https://pandas.pydata.org (https://pandas.pydata.org (https://pandas.pydata.org)

pandas is an open source, BSD-licensed library providing high-performance, easy-to-use data structures and data analysis tools for the Python programming language.

Resources

- 1. Ch 5-6 in Python for Data Analysis, 2nd Ed, Wes McKinney (UCalgary library and https://github.com/wesm/pydata-book))
- Ch 3 in Python Data Science Handbook, Jake VanderPlas (Ucalgary library and https://github.com/jakevdp/PythonDataScienceHandbook)
 (https://github.com/jakevdp/PythonDataScienceHandbook)

Let's explore some of the features.

First, import Pandas, and Numpy as a good companion.

```
In [38]: ▶ import numpy as np
import pandas as pd
```

Create pandas DataFrames

There are several ways to create Pandas DataFrames, most notably from reading a csv (comma separated values file). DataFrames are 'spreadsheets' in Python. We will often use df as a variable name for a DataFrame.

If data is not stored in a file, a DataFrame can be created from a dictionary of lists

where dictionary keys become column headers.

An alternative is to create from a numpy array and set column headers seperatly:

```
In [39]: # From a numpy array
df = pd.DataFrame( np.arange(20).reshape(5,4), columns=['alpha', 'beta', 'gam
df
```

```
Out[39]:
               alpha beta gamma delta
            0
                   0
                                  2
                                         3
            1
                   4
                         5
                                  6
                                         7
            2
                         9
                   8
                                 10
                                        11
            3
                   12
                        13
                                 14
                                        15
                  16
                        17
                                 18
                                        19
```

```
In [40]: 

# checking its type
type(df)
```

Out[40]: pandas.core.frame.DataFrame

Indexing

Loading [MathJax]/extensions/Safe.js

Accessing data in Dataframes is done by rows and columns, either index or label based.

```
# select a column
In [41]:
              df['alpha']
    Out[41]: 0
                     0
              1
                     4
              2
                     8
              3
                    12
              4
                    16
              Name: alpha, dtype: int32
In [42]:
              # select two columns
              df[['alpha', 'gamma']]
    Out[42]:
                  alpha gamma
               0
                     0
                             2
               1
                     4
                             6
               2
                     8
                            10
               3
                    12
                            14
                    16
                            18
```

```
# select rows
In [43]:
              df.iloc[:2]
   Out[43]:
                 alpha beta gamma delta
              0
                    0
                         1
                                 2
                                       3
              1
                         5
                                 6
                                       7
                    4
In [44]:
          # select rows and columns
              df.iloc[:2, :2]
   Out[44]:
                 alpha beta
                    0
                         1
              0
              1
                         5
In [45]:
          # select rows and columns, mixed
              df.loc[:2, ['alpha', 'beta']]
   Out[45]:
                 alpha beta
              0
                    0
                         1
              1
                    4
                         5
```

DataFrame math

Similar to Numpy, DataFrames support direct math

```
In [46]:
            # direct math
               df2 = (9/5) * df + 32
               df2
    Out[46]:
                   alpha beta gamma delta
                0
                    32.0 33.8
                                  35.6
                                        37.4
                1
                    39.2 41.0
                                  42.8
                                        44.6
                2
                    46.4 48.2
                                  50.0
                                        51.8
                3
                    53.6 55.4
                                  57.2
                                        59.0
                    60.8 62.6
                                  64.4
                                        66.2
```

```
In [47]: 

# add two dataframes of same shape

df + df2
```

```
Out[47]:
               alpha beta gamma delta
                 32.0
                      34.8
                               37.6
                                      40.4
            1
                 43.2 46.0
                               48.8
                                      51.6
            2
                 54.4 57.2
                               60.0
                                      62.8
            3
                 65.6 68.4
                               71.2
                                      74.0
                 76.8 79.6
                               82.4
                                      85.2
```

DataFrame manipulation

Adding and deleting columns, as well as changing entries is similar to Python dictionaries.

Note that most DataFrame methods do not change the DataFrame directly, but return a new DataFrame. It is always good to check how the method you are invoking behaves.

```
In [49]:  # add a column
df['epsilon'] = ['low', 'medium', 'low', 'high', 'high']
df
```

epsilon	delta	gamma	beta	alpha		Out[49]:
low	3	2	1	0	0	
medium	7	6	5	4	1	
low	11	10	9	8	2	
high	15	14	13	12	3	
high	19	18	17	16	4	

```
In [50]:
              # What is the size?
              df.shape
    Out[50]: (5, 5)
In [51]:
           ₩ # delete column
              df_dropped = df.drop(columns=['gamma'])
              df_dropped
    Out[51]:
                  alpha beta delta epsilon
               0
                      0
                           1
                                 3
                                        low
               1
                      4
                           5
                                 7 medium
                2
                           9
                      8
                                 11
                                        low
                3
                     12
                          13
                                15
                                       high
                4
                     16
                          17
                                19
                                       high
              # the original dataframe is unaffected
In [52]:
              df
    Out[52]:
                  alpha beta gamma delta epsilon
               0
                      0
                           1
                                   2
                                          3
                                                low
               1
                      4
                           5
                                   6
                                         7
                                            medium
               2
                      8
                           9
                                   10
                                         11
                                                low
                3
                                               high
                     12
                          13
                                   14
                                         15
                4
                     16
                          17
                                   18
                                               high
                                         19
```

Let's create a copy and assign new values to the first column:

```
In [53]:

    df copy = df.copy()

               df_{copy}['alpha'] = 20
               print(df)
               print(df copy)
                  alpha
                           beta
                                 gamma
                                         delta epsilon
               0
                       0
                                      2
                                              3
                                                     low
                              5
                                              7
               1
                       4
                                      6
                                                  medium
               2
                       8
                              9
                                     10
                                                     low
                                             11
               3
                      12
                             13
                                     14
                                             15
                                                    high
                      16
                             17
                                             19
                                                    high
                                     18
                  alpha
                           beta
                                 gamma
                                          delta epsilon
               0
                      20
                                      2
                                              3
                                                     low
                              5
                                              7
                      20
                                                  medium
               1
                                      6
               2
                      20
                              9
                                     10
                                             11
                                                     low
               3
                      20
                             13
                                     14
                                             15
                                                    high
                      20
                             17
                                     18
                                             19
                                                    high
```

DataFrames can be sorted by column:

```
# sorting values
In [54]:
            M
               df.sort_values(by='epsilon')
    Out[54]:
                               gamma delta epsilon
                   alpha beta
                3
                      12
                            13
                                    14
                                           15
                                                  high
                4
                      16
                            17
                                    18
                                           19
                                                 high
                0
                       0
                             1
                                     2
                                           3
                                                  low
                2
                       8
                             9
                                    10
                                           11
                                                  low
                1
                       4
                             5
                                     6
                                           7
                                              medium
```

Load data from file

Most often data will come from somewhere, often csv files, and using pd.read_csv() will allow smooth creation of DataFrames.

Let's load that same heart-attack.csv that we used in Numpy before:

After loading data, it is good practice to check what we have. Usually, the sequences is:

- 1. Check dimension
- 2. Peek at the first rows
- 3. Get info on data types and missing values

Loading [MathJax]/extensions [Safe is rize columns

```
# Check dimension (rows, columns)
In [56]:
               data.shape
    Out[56]: (398, 9)
In [57]:
               # Peek at the first rows
               data.head()
    Out[57]:
                                                                                   model
                   mpg cylinders displacement horsepower weight acceleration
                                                                                          origin car name
                                                                                    year
                                                                                                  chevrolet
                   18.0
                                8
                                          307.0
                                                                3504
                                                                             12.0
                0
                                                         130
                                                                                      70
                                                                                              1

Summarize values

What is the mean, std, min, max in each column?

```
In [60]: ► data.mean()
```

C:\Users\Owner\AppData\Local\Temp\ipykernel_7332\531903386.py:1: FutureWarn
ing: Dropping of nuisance columns in DataFrame reductions (with 'numeric_on
ly=None') is deprecated; in a future version this will raise TypeError. Se
lect only valid columns before calling the reduction.
 data.mean()

```
Out[60]: mpg 23.514573
cylinders 5.454774
displacement 193.425879
weight 2970.424623
acceleration 15.568090
model year 76.010050
origin 1.572864
dtype: float64
```

```
In [61]: 

# where are the other columns? Check data types
data.dtypes

Out[61]: mpg float64
```

cylinders int64 float64 displacement object horsepower int64 weight acceleration float64 model year int64 origin int64 car name object dtype: object

Notice that many columns are of type object, which is not a number. Maybe this has to do with missing values? We know from peeking at the first rows that there are '?' values in there. Let's replace these with the string NaN for not-a-number.

```
In [62]: # replace '?' with 'NaN'
data = data.replace({'?': 'NaN'})
data.head()
```

Out[62]:

	mpg	cylinders	displacement	horsepower	weight	acceleration	model year	origin	car name
0	18.0	8	307.0	130	3504	12.0	70	1	chevrolet chevelle malibu
1	15.0	8	350.0	165	3693	11.5	70	1	buick skylark 320
2	18.0	8	318.0	150	3436	11.0	70	1	plymouth satellite
3	16.0	8	304.0	150	3433	12.0	70	1	amc rebel sst
4	17.0	8	302.0	140	3449	10.5	70	1	ford torino

Pandas knows that 'NaN' probably means that numbers are missing. Now we can convert the data type from object to float

```
In [63]:
          # convert dtypes
             float cols = [col for col in data.columns if col !="car name"]
             data[float_cols] = data[float_cols].astype('float')
             data.dtypes
   Out[63]: mpg
                             float64
             cylinders
                             float64
                             float64
             displacement
             horsepower
                             float64
             weight
                             float64
             acceleration
                             float64
                             float64
             model year
             origin
                             float64
             car name
                              object
             dtype: object
```

We could have loaded the data with the na_values argument to indicate that '?' means missing number:

```
data = pd.read_csv('auto-mpg.csv', na_values='?')
In [64]:
             data.dtypes
    Out[64]: mpg
                              float64
             cylinders
                                int64
             displacement
                              float64
             horsepower
                              float64
             weight
                                int64
             acceleration
                              float64
                                int64
             model year
                                int64
             origin
             car name
                               object
             dtype: object
```

This worked nicely. Now we can describe all columns, meaning printing basic statistics. Note that by default Pandas ignores NaN, whereas Numpy does not.

In [65]:	data.describe() # ign	ores NaN

0	4	.г.	- 1	- 7	Ι.

We could be interested by these statistics in each of the genders. To get these, we first group values by gender, then ask for the description. We will only look at age for clarity

In [66]: ▶	data.g	groupby	(by='orig	gin').des	cribe	e().mp	og		
Out[66]:		count	mean	std	min	25%	50%	75%	max
	origin								
	1	249.0	20.083534	6.402892	9.0	15.0	18.5	24.00	39.0

Find NaNs

How many NaNs in each column?

We can ask which entries are null, which produces a boolean array

In [67]: ► data.isnull()

Out[67]:

		mpg	cylinders	displacement	horsepower	weight	acceleration	model year	origin	car name
	0	False	False	False	False	False	False	False	False	False
	1	False	False	False	False	False	False	False	False	False
	2	False	False	False	False	False	False	False	False	False
	3	False	False	False	False	False	False	False	False	False
	4	False	False	False	False	False	False	False	False	False
;	393	False	False	False	False	False	False	False	False	False
;	394	False	False	False	False	False	False	False	False	False
;	395	False	False	False	False	False	False	False	False	False
;	396	False	False	False	False	False	False	False	False	False
;	397	False	False	False	False	False	False	False	False	False

398 rows × 9 columns

Applying sum() to this boolean array will count the number of True values in each column

```
In [68]:

    data.isnull().sum()

   Out[68]: mpg
                               0
              cylinders
                               0
              displacement
                               0
              horsepower
                               6
              weight
                               0
              acceleration
                               0
              model year
              origin
                               0
              car name
                               0
              dtype: int64
```

We get complementary information from info()

```
In [69]:
          M data.info()
             <class 'pandas.core.frame.DataFrame'>
             RangeIndex: 398 entries, 0 to 397
             Data columns (total 9 columns):
